APPENDIX (B.1.)

```
C                              ===========
C       Sub-Program Name :     '  CONVOL  '
C       -----------------      '==========='
C
C       Purpose and General Description :
C       ---------------------------------
C       This Routine :
C       1. produces the smoothed-out version of the probability distn
C          mixing both Discrete and continuous parts in the convolution;
C       2. compresses the convolution DP(.) onto the single probability
C          SP(.) ; and similarly for DPD(.) onto SPD(.), which in turn
C          are the" discrete contributions" to the smoothed-out distribution.
C          These discrete contributions, or "jumps", are spread out in the
C          distribution by the convolution process of course, and are
C          irretrievable by the simple process of just subtracting the
C          TRINOMIAL terms.
C       3. Collapses the SP(.)+s that are too small or zeros such that
C          their cumulative sum is below the TOLERance level defined
C          by TOLER...
C
C       The Descriptions of the Subroutine Parameters  are:
C       (1) INPUT Parameters :
C           N              the number of probabilty cells .
C           SCALE          the scaling factor adjusted with every compression
C                          of the convolved distribution ,initially set at 1/N .
C           QMIN,QMAX      minimum and maximum values of average quality score
C                          initially set at 0,1 respectively .
C
C           TOL            Maximum Tolerable total of absolute discrepancies in
C                          the probability that can be forsaken for compression.
C       (2) OUTPUT Parameters :
C           QMIN,QMAX      give the values after compression processes .
C           SCALE          the scaling factor of the distribution after compressions.
C           KOUNT          Controls number of convolutions so as to meet the
C                          required number determined by the INPUT parameter KN .
C           AMU            the mean of the Normal Distribution such that the
C                          proportion below 0.0  is  equal to p0 (predetermined).
C           SIGMA          standard deviation for Normal Dist. (set equal to 1) .
C           IFAULT         Failure parameter supposed to score 0 if subroutine is
C                          successful ,and a positive integer otherwise .
C           IFLAG          a checking indicator to show whether cell compression
C                          has taken place or not (0 or 1 ) .It could also be used
C                          as a counter for number of compressions made as herebelow.

C
C                          ================
C     Name of Program :    "   DRAMP.FOR   "
C     ----------------     ================
C
C     Purpose :
C     ---------
C     This FORTRAN Program  is responsible for the production of the
C     numerical distributions for the r.v. of the Ramp average quality
C     function . It prepares the information for and then uses the FORTRAN
C     subroutine CONVOL . This is as discussed theoretically in Chapter III .
C     The results of this Program are shown in Appendix () in the form of
C     tables of the distribution for different sample sizes .
C
C
C     Subroutines Called by the Program :
C     -----------------------------------
C     CONVOL            performs the Convolution process ( It is listed
C                       and explained in appendix() ).
C     INVPHI (or GAUINV)      for finding the Normal percentage point given
C                       the cumulative probability .
C     ALNORM            the function that evaluates the Cumulative probability
C                       for a given percentage point of a standard Normal r.v.
C                       ( Due to I.D. Hill  Applied Statist. Vol 66 )

C
C                        ==============
C       Program Name :   "  TESTC.FOR  "
C       -------------    ==============
C       Purpose :
C       ---------
C       To find and properly tabulate the percentage points of the tabulated
C       distributions of the Ramp r.v. ( average quality function ) , under the
C       assumption of a Normally distributed process with variance  1  and a mean
C       such that the proportion below 0 is fixed at p0 . It uses the tabulated
C       results of the convolved Distribution  and so a file containing such
C       data is OPENned as an INPUT media . Extensive use of interpolation methods,
C       especially cubic splines from FORTRAN  NAG Routine Library ,is made to
C       facilitate the purpose of this Program .
C       Results and output :
C       --------------------  Results are given in the tables of the Test Criteria
C       displayed in appendix (C.2.) .
C
C       Subroutines CALLed and used :
C       -----------------------------
C       ( a)  Numerical Analysis Group ( NAG ) routines are :
C           E01BAF      determines a cubic-spline interpolant to a set of data
C           E02BBF      evalutes cubic-spline from its B-spline (see FORTRAN NAG Library Manual Mark 10 Vol 2 )
C       ( b)  Other specially-designed  routines  are  :
C             BINOM       evaluates the standard Cumulative Binomial Probability
C                         for given p , n and r   ......
C             FLOG        finds the natural logarithm of the factorial of an
C                         integer ( useful in   evaluating  BINOMial Coefficients)
C             FUN         evaluates a Zero of a numerical function within a level
C                         of accuracy of the parameter ETA1 . Used to locate the
C                         position of the "jump" for interpolation purposes .

C
C       Program Name :          ==============
C       -------------           '  EQUIV.FOR  '
C                               '=============='
C
C       Purpose :
C       ---------
C       1.  To establish the "equivalence" between the different
C       schemes on the basis of the ( two points of the ) O.C. curve .This
C       is done as the discussion in Chapter III  shows  . It gives as its
C       output the parameters of the 'equivalent'  "Two-class"  Attribute  ,
C       "Ramp"  , "S"  and "Sigma" plans .
C
C       2. The above is achieved  by  firstly  finding the (p0(2) , 1-Beta)
C        O.C. point of the Ramp case after arbitrarily chosing the (AQL,Alpha)
C       point and hence determine the parameters of Ramp plan .These parameters
C       give the decision rules for the Ramp case under the O.C. predetermined
C       specifications . The Output gives the Ramp parameters for the Ramp
C       decision rules . Simple interpolation methods are used to find the
C       the matching points between the grid-points of the give Ramp
C       percentiles .
C
C       Input Data and Medium :
C       ---------------------- The  Output  created  by the Program DRAMP.FOR
C       is stored in the file SUMKN.DAT as suitable percentage points of the
C       Ramp Convlved Distribution .This is fed as an INPUT Data file to this
C       program .
C
C       Routines and Sub-programs used :
C       -------------------------------
C       1. CHISQD       :gives the Percentage points for any given Chi-squared
C                       distribution level .
C       2. MATCH        : gives the parameters  (n and  c ) of the "Two-class"
C                       attribute scheme that matches the given two O.C. points.
C       3. INVPHI(or GAUINV ) and ALNORM        :these are the usual routine
C                       for the Inverse of the Normal and its lower tail cumulative
C                       probability ,respectively .
C
C       {NB : The equivalent S-plan and Sigma-plan have their parameters
C        determined by solving systems of simultaneuos equations as shown
C        below for the Sigma-plan and Hamaker's method for the S-plan } .

C        Number of Simulations is NSIMUL=2000  so as to maintain a level of
C        precision at Alpha= 1%   ; the Number of Normal r.v.'s
C        used in the simulation is about 800,000 r.v.'s . Details of the methods
C        implemented are imbedded as Comments inside the Program .
C
C        Input Data and Random Numbers Used :
C        -----------------------------------
C        1.The Normal r.v.'s where prepared prior to the running of this program.
C         They were generated using Brent Algorithm and  randorm uniform number
C         generator RAN together with other facilities of the University of Essex
C         Computer ( DEC-10 ) .These are then shuffled in blocks of 1000 at a time
C         and stored  in a Data File named  NORVS.DAT ( about 800000 r.v.'s in
C         about 6000 computer blocks ) .
C
C        2. The "equivalence" data are also used of course .
C
C        Routines and Sub-Programs CALLed :
C        ---------------------------------
C        1. NEWRVS        :a routine to READin the r.v.'s in blocks of a 1000 at
C                          a time once the 1000 in the buffer has been consumed .
C        2. GAMMA         : to READin the required value of GAMMA , the fraction
C                          of "Contamination" . It is the proportion of the
C                          "contaminant" in the process .
C        3. STNORM        : Sub-program generator of Normal r.v.'s    .
C

      WRITE(NOUT,99903)
C
C     Let  EMUC  and EMUO  denote the means  of the Contaminant dist. and
C     the Original  dist. respectively . Let SIGC and SIGO be the respective
C     standard deviations for the component normals . Set  EMUC = 0.0 and
C     solve for EMUO
C     and SIGC  ( since SIGC = D * SIGO ) by using the facts that the overall
C     variance should equal  1 , and  that the overall proportion defective
C     is PROP ( given ) . Hence ,
C
C     ( PROP :- GAMMA * PHI  ( -O/SIGC) )/ ( 1-GAMMA)   =  PHI(-EMUO/SIGO)
C
   15 EMUC = C.C
C
C     The above discussion imply that
C                                  -1
C           EMUO = - SIGO * PHI   (PROP - GAMMA/2)/(1-GAMMA)
C
C     which will only make sense if the argument is +ve and reasonably (0.001)
C     away from 0 .Strictly speaking if  PROP < GAMMA/2   there is no solution.
C     So, we have 3 parameters and 2 equations which suggest we should
C     determine SIGO and EMUO in terms of GAMMA for agiven PROP
C
      GAMMA= GAMMA * 0.9
      WRITE(6,10) GAMMA
   10 FORMAT(' * Negtive  probblty  argt ,i.e., GAMMA
     +  too large for  PROP  ,GAMMA is DESCALED into',F7.4,' *')
      GO TO 5
   20 ONEMG=1.0 - GAMMA

     1 MODE='BINARY')
```

```
C       Read-in the first block of a 1000 standard normal r.v.'s
C
        READ(21) XN
C

C           Start of Simulation  sampling
C       (( ISIM is the count of the Simulationsamples made))
C
  100   ISIM = ISIM + 1
        NMAX = NATT
C
C       3. In the following we are assuming we have a block of 1000 r.v.'s
C          in the buffer array XN(1000) .Now, we select a sample for the
C       Attribute case sequentially relying on the randomization of the
C       shuffling done to the normal variates prior to storage on disc .
C                        Note that if the supply of the
C       current 1000 r.vs. is nearly exhausted MORE is supplied from storage
C       by a  CALL  NEWRVS( MORE , J) which reads more r.v.'s from the OPENed
C       disc file  NORVS.DAT ...This happens whenever the remaining r.v.'s
C       are not exactly enough to make a new different sample . The Subroutine
C       NEWRVS  provides MORE r.v.'s . THat is , making a completely new different
C       set of 1000   uncycled r.v.'s from which further simulation samplings
C       are made ..
C
        DO  999   I = 1,NMAX
        J=J-1
        MORE=1001-J
        ITH = MORE
        X(I) = XN(ITH)
        IF ( J .LE. 1 ) CALL NEWRVS(MORE,J)
  999   CONTINUE
C
C       Notice : A shuffling process is already done on the stored r.v.'s
C       prior to storing them . This is done by a randomisation procedure
C       and that is why we are reading and using the stored r.v.'s sequentially
C       Shuffling is meant to break down any pattern or sequence in the pseudo-
C       random  variates used .
C
C       4. The random contamination procedure for the NMAX sample follows .
C          (NMAX is the sample size for the attribute case , the maximum n ).
C         NOTES on possible methods :
C        (a). The ALIAS METHOD is suggested here to speed up the operation
C          of random contamination .The Alias Table of Li and Fi is generated
C          by SUBROUTINNE ALIAS .The Alias table is then used as follows:
C          - Generate ,independently, two r.v.'s  U1 , U2  {~ Uniform(0,1) }.
C          - Select cell  i=INT(nmax * U1) + 1 ; if  U2 < Fi then IRC ,the
C          no. of contaminated r.v.'s in the sample , is IV(i) ; and otherwise
C          IRC=IV( L(i) ), where IV(i)=i-1 (for i=1,nmax+1 ) is the set of the
C          random number of contaminated r.v.'s .
C         (b). The DIRECT method is as follows :
C          -Generate NMAX uniform r.v.'s ,UU(),{independent of the shuffling
C          uniforms and of the normals creator } .
C          -Compare each of the UU(j) uniforms with GAMMA and decide :
C           if UU(j) > GAMMA  then XC(j)=X(j)*sigo + EMUO , otherwise
C           contamination takes place ,i.e., XC(j)=X(j)*sigc + EMUC
C           where XC  and  X   are the contaminated and the pre-contamination
C           samples , respectively....
C
C

        UNIF = G05CAF(UNIF)
        UU(I) = UNIF
        XI = X(I)
        XII= XI * SIGO + EMUO
        IF ( UNIF .LE. GAMMA ) XII = XI * SIGC + EMUC
        XC(I) = XII
 1500   CONTINUE
C

C
C       This XC(I) sample is a  GAMMA-contaminated normal sample from :
C           F  = (1 - GAMMA) * PHI(EMUO ,SIG) + GAMMA * PHI(EMUC ,SIG)
C       which is a mixture of two normals
C                Generally , on simulating the robustness of the cantaminated
C        normal we made use of the idea of 'CONTROL VARIATE ' by use of the
C        attribute plan whose variability is controlled and by re-use of the
C        same sample data to simulate the behaviour of each of the "Equivalent"
C        plans . Note also the economisation due to the intensive use and re-use
C        of r.v.'s of the attribute largest sample to create more than one smaller
C        samples of equivalent plans per each attribute sample.

C       5. Herebelow we evaluate the contamination effects on the attribute as
C         well as preparing for assessing the effects on other "equivalent"
C         plans :
C
        NO = 0
        U1J = 0.0
        A  = 0.0

C          ****************  Simulation Program (2) "Lognormal" ************
C                              ==============
C        Program Name :          ' LOGNOR.FOR '
C        --------------          '============'
C
C        Purpose :
C        --------- Same as in Program CONTAM.FOR except that this is one
C        is for study of robustness in case of a Lognormal  process .
C
C        Input Data :
C        ------------ ( same as in the Program CONTAM.FOR )
C
C        Routines and Sub-Programs :
C        ---------------------------
C        ( same as  in CONTAM.FOR ) but  also :
C
C        1. ZERO          :to find the Zero of a transcedental function that
C                          satisfies the requirement that the overall variance
C                          of the Lognormal process should be 1 . ZERO relies
C                          on the subroutines FUN and DFUN that compute  values
C                          of the function and its derivative , respectively .

C
      DATA EPS / 0.001 /
C
C
      XINV = GAUINV(PROP,IFAULT)
      IF(IFAULT .NE. 0 ) STOP 'Inconsistent PROP '
C
C      MATCHING OF THE LOGNORMAL (or more proper to rename it "Exponormal")
C      such that it has p0 proportion defective and an overall variance = 1 .
C
C      Notes :
C      (a) If  Y is N(Mstar , Sigstar) then  X=EXP( Y ) is  LOGNORMAL( M ,S2)
C         with mean  M = EXP( MUstar + Sigstar**2)  and  variance
C         S2 = EXP(2.*MUstar +  Sigstar*Sigstar) * ( EXP(Sigstar*Sigstar) - 1 )
C      (b) Suppose , for a +ve domain ,
C            ln Astar = MUstar + k * Sigstar
C                          -1
C          where      k=PHI  ( p0 )
C          then we should look into transforming a N(MUstar+ln Astar ,Sigstar)
C          into a  lognormal(M,S2)
C
      AK = XINV
C          which is -ve for  p0 < 0.5
C
C      (c) To match the lognormal variance S2  to  1 ( and since
C           MUstar=-k * Sigstar) we have to solve for Sigstar in :
C           exp(-2*K*Sigstar + Sigstar**2) * ( exp(Sigstar**2)-1)-1 = 0
C         ( i.e. find the ZERO of this Transcendental function )
C          Sigstar will determine MUstar .The ZERO is found by the ROUTINE
C
      CALL ZERO ( SIG0 , EPS , AK ,IFAULT)
      IF (IFAULT .NE. 0 ) STOP 'Derivat. DFUN is 0 for Newt.-Ral.'
      SIGSTR = SIG0
      AMUSTR = - AK * SIGSTR
C
C      (d) Now , the Normal to be transformed into a Lognormal needs to
C          have a mean  MUstar and standard deviation Sigstar , so :
C                  YN(I) = Sigstar * XN(I) + MUstar
C           is a N( MUstar , Sigstar) , which is used in  [4] below
C           as well as
C
      ALNA = AMUSTR + AK * SIGSTR
      ASTAR = EXP( ALNA )
C
C      Now , having   matched   the Lognormal and its  parameters ( so as
C      to give a Variance = 1 and a prop. defective=p0  ) , we use the
C      pseudo-random normal variates and  simulate the lognormal  randomly
C      selected samples as in the following steps :
C
C      1.       As done above READin  current parameters the EQUIVALENT plans
C               to be compared (NATT,IC),(NRAMP,TRAMP,B,P0(2)),(NSIGMA,AKSGMA),
C               and (NSPLAN,QSPLAN) ,...,etc.
C
      BB = 0.1
      DO 9000 JB=1,4
      BB = BB + 0.4
      IF(IEXIS(JB) .NE. 0 ) GO TO 15
      WRITE(0,19) BB
      GO TO 9000
   19 FORMAT(/,'  At B =',F5.2,' there is a Non-Existence case ',/)
   15 Natt= NAT(JB)
      ic=ICA(JB)
      nramp=NRA(JB)
      tramp=TRA(JB)
      nsigma=NSG(JB)
      aksgma=AKG(JB)
      nsplan=NSP(JB)
      qsplan=QSP(JB)
C
C
C      2. Initialise the sums , sums of squares,the number of simulation
C         samplings, etc....
C
      SU1J=0.0
      SU1J2=0.0
      SD2J=0.0
      SD2J2=0.0
      SD4J=0.0
      SD4J2=0.0
      SD5J=0.0
      SD5J2=0.0
      ISIM = 0
      sumneg=0.0
C
      J=1001
      OPEN(UNIT=21,DEVICE='DSK',FILE='NORVS.DAT',ACCESS='SEQIN',
     + MODE='BINARY')
C
C      Read-in the Initial block of 1000 of standard normal r.v.'s :
C
      READ(21) XN
C
  100 ISIM = ISIM + 1
      NMAX = NATT
C
C      3. In the following we are assuming we have a block of 1000 r.v.'s
```

```
C          in the buffer array XN(1000) .Now, we select a sample for the
C       Attribute case sequentially relying on the randomization of the
C       shuffling done to the normal variates prior to storage on disc .
C                        Note that if the supply of the
C       current 1000 r.vs. is nearly exhausted MORE is supplied from storage
C       by a  CALL  NEWRVS( MORE , J) which reads more r.v.'s from the OPENed
C       disc file  NORVS.DAT ...This happens whenever the remaining r.v.'s
C       are not exactly enough to make a new different sample . The Subroutine
C       NEWRVS  provides MORE r.v.'s . THat is , making a completely new different
C       set of 1000   uncycled r.v.'s from which further simulation samplings
C       are made ..
C
        DO  999   I = 1,NMAX
        J=J-1
        MORE=1001-J
        ITH = MORE
        XNORM = XN(ITH)
C        4. This XNORM is a N(0,1) to be transformed into a N(MUstar,Sigstar)
C          which is in turn "lognormalled" as Lognormal(M,S2=1) as follows :
C
        YNORM = SIGSTR * XNORM + AMUSTR
        YEXP = EXP ( YNORM )
C        YEXP comes from a Lognoral with p0 below Astar( >0 ) .. and for this
C        to mimick our process we require the displacement :
C
        XEXP = YEXP - ASTAR
        X(I) = XEXP
        if(xexp .le. 0.0) sumneg=sumneg+1.
        IF ( J .LE. 1 ) CALL NEWRVS(MORE,J)
  999   CONTINUE
C
C       Now , we have an ATTRIBUTE complete  sample from a lognormal process ...
C
C       Notice : A shuffling process is already done on the stored r.v.'s
C       prior to storing them . This is done by a randomisation procedure
C       and that is why we are reading and using the stored r.v.'s sequentially
C       Shuffling is meant to break down any pattern or sequence in the pseudo-
C       random  variates used .
C
C          (NMAX is the sample size for the attribute case , the maximum n ).
C

C
C       This X(1) is a  Lognormal sample from a population with variance=1
C              Generally , on simulating the robustness of the Lognormal
C        we made use of the idea of 'CONTROL VARIATE ' by use of the
C        attribute plan whose variability is controlled and by re-use of the
C        same sample data to simulate the behaviour of each of the "Equivalent"
C        plans . Note also the economisation due to the intensive use and re-use
C        of r.v.'s of the attribute largest sample to create more than one smaller
C        samples of equivalent plans per each attribute sample.

C       5. Herebelow we evaluate the Lognormal effects on the attribute as
C         well as preparing for assessing the effects on other "equivalent"
C         plans :
C
        NO = 0
        U1J = 0.0
        A  = 0.0
        DO 2500 I = 1, NMAX
  2500  CONTINUE
        IF ( NO .LE. IC ) U1J = 1.0
        SU1J = SU1J + U1J
        SU1J2 = SU1J2 + U1J * U1J
C

C
C
C       Choice of initial seed of the iteration by  using simple
C       search and a bisection methods so as to be in the neighbourhood of
C       the ZERO .This speeds up the convergence process when using the
C       Newton-Ralphson iterative method used later below .
C               Try the lowest possible following lower and upper arbitrary
C       values  :
C
  110   XA = 0.1
        XB = 1.0
   20   FA = FUN( XA ,AK)
        FB = FUN( XB , AK)
C
C       where FUN is the function to be solved for the zer .(( DFUN used later
C        is the derivative of FUN )) . Check that (XA,XB) is the right interval
C        for the solution (and possibly that XA or XB is the solution ) :
C
        XO = XA
        IF ( ABS(FA) .LE. EPS) RETURN
        XO = XB
        IF ( ABS(FB) .LE. EPS) RETURN
        ADD = 1.0
        FAFB = FA * FB
        IF ( FAFB ) 70,70,35
   35   XA = XB
        XB = XB + ADD
        GO TO 20
   70   XO = ( XA + XB )/2
C
C       End of Bisection and search .... XO is the seed for the Newton-Ralphson
C       iterations  ..... Possibly XO is the ZERO of FUN :
C
        XI = XO
   75   FI = FUN ( XI , AK )
        IF ( ABS(FI) .LE. EPS) RETURN
        DFI = DFUN ( XI , AK)
C
C       We should not worry that the derivative DFI is  0 (or "zero-prone")
C       but a check is  advisable ; thus
C
        IFAULT = 1
        IF ( ABS( DFI-0.0001) .LE. 0.0 ) RETURN
        IFAULT = 0
        XI = XI - FI / DFI
        XO = XI
        GO TO 75
        RETURN
```

```
      END
C

Tables to show Equivalence results and robustness under the Uniform Model

The tables below give the parameters for the four equivalent schemes . Each of these four schemes is shown on a row in the tables .The Ramp case is given on the first row where for a given E value the first entry is an integer which indicates that a plan "exists" if the integer value is 1 and "non-existent" if the value is 0 . Of course with "non-existence" there are no reported equivalents and this shows clearly in the tables . The other entries are the Ramp sample size , the E value , the test criterion t , and p0(2) value of the proportion defective of the second equivalence point ,in that order .

On the second row we have the parameters for the equivalent two-class attribute case . Its first entry is the n_{95} (the sample size that satisfies equality in (5.1.) in Chapter (V)) . The second entry is n_{50} satisfying the equality in the inequality (5.2.) . The last entry on the row is the attribute acceptance number , c .

The third row gives the sample size and the test criterion for the S-plan . The fourth row gives them in the case of σ-plan .

For conservation of space the robustness for the Uniform model is also reported on the right side columns of the following tables .

Appendix (C.4.)

Performance of the Sample Sizes under Equivalence of Different Schemes

Description of the tables :

The tables are composed of a number of sub-tables each representing a level of AQL shown at the right top corner . The B values are shown on the top of each set of parameters , while the values for the Ramp sample size are shown on the left of each sub-table .

For any B on this table there are three columns of sample size The first column is for equivalent two-class plan , the second for the S-plan and the third one for ●-plan .

Each row has a ramp n that is equivalent to each n in each subset of three.But it should be remembered that between the subsets the background O.C. curves are different .Also note that the "equivalence" values of n for the attribute case are chosen such that the O.C. at the 95% point is as close as possible to (AQL,95%) .

We should also note that the values of the 50% indifference point on the O.C. curve behind the "equivalences" in these tables have a proportion defective, p0(2), which is decreasing with B .In a way this is responsible for the higher sample sizes as B increases .This is due to the general rule that a smaller p0(2) implies more stringency of the O.C. discrimination and hence a larger sample size . These values of p0(2) are shown in parantheses beneath their relevent subset of sample sizes .

Behaviour of Sample Size in the Different "Equivalent" Schemes

---

n.b. :

(1) The values in the brackets show, P0(2), the proportion defective for the 50 % indifference point of the equivalence O.C. curve .

(2) Some of these results are reflected graphically in Chapter (IV).

Appendix (F.1.)

Robustness Results for Lognormal and Contaminated Normal processes

The Performance of the Schemes under Lognormal and Contaminated Normal Processes is given below in terms of the Probability of Acceptance for the equivalent sets of plans :

for AQL= 0.01390 (at 95%) :

				Lognormal	Contaminated-Normal Robustness									
					D = 1			D > 1

Appendix (F.2.)

Table (5.4.2) : Results of The Variance-Effect acceptance Probability for "Ramp" and " &-plan" at the given AQL

Note :

1. In this table for each value of B there are two rows .The first row shows the "Pa" resulting from variance changes for RAMP while the second row shows that for &-plan for which "n" is given at the end of its row.
2. The value of the changed variance does not appear on the table for space saving since it is easy to evaluate .For each double entry it is equal to the quotient of the bracketed B (on the left) over the top column B value . Such values of & are given in the subsidiary table annexed to this table.
3. The value of the specific AQL is given below as p0 .
4. The second column in each sub-table gives the value of the test criterion which is t for the Ramp and K for the &-plan . If a value of -1.0000 is given for t this indicates "Non-existence" problem and hence the label "NE" shown below .("Non-existence" is defined and discussed elsewhere) .

The following table is useful in giving the true changes in & for the above tables :

Value of True &= B* / B

(B* : is the planned value , and B is the True value)

B* :	0.5	0.7	0.9	1.1	1.3	1.5	1.7	1.9
B								
0.5 :	1	0.714	0.556	0.455	0.385	0.333	0.294	0.263
0.7 :	1.400	1	0.778	0.636	0.538	0.467	0.412	0.368
0.9 :	1.800	1.286	1	0.818	0.692	0.600	0.529	0.474
1.1 :	2.200	1.571	1.222	1	0.846	0.733	0.647	0.579
1.3 :	2.600	1.857	1.444	1.182	1	0.867	0.765	0.684
1.5 :	3.000	2.143	1.667	1.364	1.154	1	0.882	0.789
